Lund University, Box 118, 22100 Lund, Sweden

ABSTRACT
Nowadays, heat exchangers can be found everywhere: in heaters, in fridges, in boilers or in condensers of steam turbines. In all of these machines, the heat exchanger is a key element.

In a heat exchanger, heat is transported between two working fluids. These fluids aren’t either in contact with each other or mixed. Usually, they are separated by pipes or walls.

In this report, a typical heat exchanger problem is presented and shown how it can be solved with a numerical approach.

NOMENCLATURE
- \( A \) \( \text{surface area of the heat exchanger, m}^2 \)
- \( C \) \( \text{heat capacity flux, W/K} \)
- \( Q \) \( \text{heat flux, W} \)
- \( T \) \( \text{temperature, K} \)
- \( \Delta T \) \( \text{temperature difference, K} \)
- \( c \) \( \text{specific heat, J/kg K} \)
- \( k \) \( \text{heat transfer coefficient, W/m}^2\text{K} \)
- \( \dot{m} \) \( \text{mass flux, kg/s} \)

Subscripts
- \( h \) \( \text{hot fluid} \)
- \( c \) \( \text{cold fluid} \)

Superscripts
- \( ' \) \( \text{outlet} \)

INTRODUCTION
Fig. 1 shows a counter flow heat exchanger. While the “cold” medium flows from the right-hand side to the left-hand side, the “hot” fluid flows from the left to the right.

PROBLEM STATEMENT
The first law of thermodynamic provides the energy balance of the complete system and can be written as

\[
\hat{Q} = (T_h - T_h') \cdot \dot{C}_h = (T_c - T_c') \cdot \dot{C}_c
\]

where

\[
\dot{C}_h = \dot{m}_h \cdot c_h \quad \text{and} \quad \dot{C}_c = \dot{m}_c \cdot c_c
\]

If supposed that the inlet temperatures \( (T_h, T_c) \) are known, there are still three unknown values: the outlet temperatures.
(\(T_h', T_c'\)) and the heat flux \(Q\). Therefore, a differential element is used (see Fig. 3).

![Fig. 3: Energy fluxes within two differential volume elements in a counter flow heat exchanger](image)

The energy balance for the heat, which is absorbed or released by the two streams, is:

\[
d\dot{Q} = -\dot{C}_h \cdot dT_h = -\dot{C}_c \cdot dT_c
\]

Furthermore, the following equation can also be used:

\[
d\dot{Q} = k \cdot dA \cdot \Delta T
\]

The heat transfer coefficient \(k\) is considered as a constant value all over the heat exchanger. In equation (3), \(\Delta T\) is defined as \(T_h - T_c\). But note: These temperatures are local temperatures, not the inlet temperatures.

With equation (3), equation (2) can be written as:

\[
d\Delta T = dT_h - dT_c = d\dot{Q} \left( \frac{1}{C_c} - \frac{1}{C_h} \right)
\]

If equation (3) and equation (4) are combined, one can form a differential equation out of these:

\[
d\Delta T = dT_h - dT_c = d\dot{Q} \left( \frac{1}{C_c} - \frac{1}{C_h} \right) = k \cdot dA \cdot \left( \frac{1}{C_c} - \frac{1}{C_h} \right)
\]

\[
\Rightarrow \frac{d\Delta T}{\Delta T} = k \cdot A \left( \frac{1}{C_c} - \frac{1}{C_h} \right)
\]

The differential equation (5) can be solved by integration from point “1” to point “2” (see Fig. 1).

The solution is:

\[
\ln \left( \frac{\Delta T_2}{\Delta T_1} \right) = -k \cdot A \left( \frac{1}{C_c} - \frac{1}{C_h} \right)
\]

The term \(\frac{1}{C_c} - \frac{1}{C_h}\) can be transformed with equation (1):

\[
\left( \frac{1}{C_h} - \frac{1}{C_c} \right) = \frac{1}{Q} \left( T_h - T_h' - T_c' + T_c \right) = \frac{1}{Q} \left[ (T_h' - T_c') - (T_h - T_c) \right] = \frac{1}{Q} (\Delta T_1 - \Delta T_2)
\]

If equation (7) is applied to equation (6), one gets the following equation:

\[
Q = kA \left( \frac{\Delta T_1 - \Delta T_2}{\Delta T_1} \right) = kA \left[ \frac{(T_h' - T_c') - (T_h - T_c)}{\ln \left( \frac{T_h - T_c}{T_h' - T_c} \right)} \right]
\]

Equation (8) still contains 3 unknown values. So, it’s still very hard to solve this equation. However, it can be further rearranged if equation (1) is used two times. From equation (1), one can get equation (9) and (10):

\[
T_h = T_h + \frac{C_c}{C_h} (T_c' - T_c)
\]

and

\[
Q = (T_c' - T_c) \cdot \dot{C}_c
\]

With equation (9), the right hand side of equation (8) can be written as:

\[
kA \left[ \frac{(T_h' - T_c') - (T_h - T_c)}{\ln \left( \frac{T_h - T_c}{T_h' - T_c} \right)} \right] = kA \left[ \frac{\frac{C_c}{C_h} (T_c' - T_c) - T_h + T_c}{\frac{T_h + \frac{C_c}{C_h} (T_c' - T_c)}{T_h - T_c} - T_h + T_c} \right]
\]

When this and equation (10) is applied to equation (8), the equation can be written as:

\[
(T_c' - T_c) \cdot \dot{C}_c = kA \left[ \frac{\frac{C_c}{C_h} (T_c' - T_c) - T_c + T_c}{\frac{T_h + \frac{C_c}{C_h} (T_c' - T_c)}{T_h - T_c} - T_h + T_c} \right]
\]

Since \(T_c, T_h, C_c\) and \(C_h\) are known, equation (11) has only one unknown value. But unfortunately the equation can’t be solved by hand since it’s not possible to write it in this form:

\[
T_c' = \ldots
\]
In order to solve this equation anyway, a numerical approach is chosen. This approach is shown in the next chapters.

**SOLUTION OF THE PROBLEM**

In order to get a specific value for $T'_c$ from equation (11), one can solve this problem graphically. Since both side of equation (11) can be used to calculate $Q$, $Q$ can be plotted as a function of $T'_c$, where $T'_c$ is a set of values between 283K (= $T_c$) and 363K (= $T_h$). Furthermore, the following values are considered as known:

- $T_c = 283K$
- $T_h = 363K$
- $A = 2.1 m^2$
- $C_c = 6300 W/K$
- $C_h = 8400 W/K$

The plot of the two functions looks like this:

![Graph showing the two functions plotted against $T'_c$.](image)

Fig. 4: Plot of the two side of equation (11)

Fig. 4 shows the plot of both functions. At the point where both function cross each other, there is the sought-after temperature $T'_c$. With a ruler, it’s very easy to get a solution from this figure. It’s between 330K and 340K. But this solution is not very accurate. Therefore, a little algorithm is developed.

With this algorithm, special software can be used to calculate an exacter solution for $T'_c$. The software, used for this problem is called “Scilab”.

**THE ALGORITHM**

Equation (11) is transformed once more and looks like this:

$$f(T'_c) = (T'_c - T_c) \cdot C_c - kA \frac{C_c}{C_h} (T'_c - T_c) - T'_c + T_c$$

(12)

Now, the algorithm will search for a solution of Equation (12) until $f(T'_c) = 0$. But since processors can’t handle infinite small numbers, a break criterion is introduced: If the absolute value of the $f(T'_c)$ is smaller than $10^{-3}$, then the algorithm considers this as $f(T'_c) = 0$ and stops the calculation process.

As a starting point, $T'_c$ is set to 285K. Then the difference between both sides is calculated. One can see that the difference is bigger than $10^{-3}$ (see Fig. 4). Therefore, $T'_c$ is increased by 10K ($= \Delta T$) and the difference is calculated again. This procedure is repeated until the algebraic sign of the difference changes. If this happens, the algorithm “stepped over” the solution to the equation. Therefore, $\Delta T$ is subducted, divided by two and then added to $T'_c$ again. The calculation starts again. If the algebraic sign changes again, $\Delta T$ is subducted and divided again.

To ensure that this procedure has a finite number of steps, a second break criterion is introduced: $\Delta T$ has to be higher than $10^{-7}$. If it is smaller, then the algorithm stops and $T'_c$ is considered as found.

So, basically, the algorithm starts form one side of the crossing point and tries to approximate it as near as possible. If it steps over the crossing point (because $\Delta T$ is too big), it steps back and tries a smaller $\Delta T$ and so on. Fig. 5 shows the whole procedure graphically.

![Graph showing the search for the crossing point.](image)

Fig. 5: Search for the crossing point. One can see a part of Fig. 4. The dotted line symbolizes the search procedure
IMPLEMENTATION IN SCILAB

Scilab is a free numerical computational package, similar to the commercial software Matlab.

To show how the algorithm is realized in the software, Fig. 6 shows a structural diagram, which shows all the necessary steps. The source code for the algorithm can be found in the appendix.

![Fig. 6: structural diagram of the algorithm](image)

SOLUTION

For this problem, $T'_c$ is 331.60578 K, $T'_h$ is 326.80816 K and the heat flux $Q$ equals 305271.44 W (calculated with equation (10)).

These values are very accurate because if the break criteria were set to much smaller values, e.g. $\Delta T > 10^{-9}$ and $\text{diff}(T_{ca}) > 10^{-5}$, the values wouldn’t really change.

An interesting question is how many calculation steps are required to find a solution. Fig. 7 shows the profile of the difference of the two equations (in logarithmic scale) over the number of calculated steps. The thick horizontal line represents the break criterion of $\text{diff}(T_{ca}) > 10^{-3}$. One can see, that after 43 iterations, a solution for $T_{ca}$ is found (indicated by $\text{diff}(T_{ca})< 10^{-3}$).

![Fig. 7: profile of the difference over the number of calculations](image)

CONCLUSIONS

As one can see, this algorithm is an easy, but very effective way to solve problems like this. This type of algorithm can be used for any kinds of problems when it comes to equations, which can’t be solved by rearranging but with graphical analysis.
